PUBLIC SAMPLE 03

# Verification failed. The cause is still open.

A public-surface technical review of a signed evidence record and its published verification key.

**OBSERVATION REPRODUCED / CAUSE UNESTABLISHED**

An independent verifier reproduced the signature rejection, but the available public evidence did not identify the faulty component.

## 1. Question and boundary

Could one publicly retrieved signed evidence record be verified using the published key and the documented message representation?

The original work was a self-initiated public-surface review, rather than an agreed private-beta engagement.

The boundary covered the selected record, public retrieval and verification surfaces, published key and local verification checks.

## 2. Procedure recorded in the original pilot

A fresh evidence record was retrieved directly through the public API.

The unchanged inner record was submitted to the public verifier, which reported INVALID.

The unsigned message representation was independently reconstructed outside the browser verifier.

An independent Ed25519 implementation checked the signature using the published public key.

The check was repeated using the actual retrieved key object to control for manual key reconstruction.

## 3. What was established

The independent checks reproduced INVALID for the selected record and published key.

The reconstructed message length matched the value reported by the public verifier.

The discrepancy therefore could not be localized solely to the browser verification interface.

PUBLIC SAMPLE 03 / FINDINGS AND LIMITS

## 4. Additional controls

Several alternative message representations were tested without obtaining a valid signature.

Those controls were not an exhaustive search of every possible signing representation.

A separate retrieval check found that a latest-record function returned an older object while a newer object was directly retrievable.

## 5. What remained UNESTABLISHED

The available public evidence did not establish whether the mismatch arose from key publication, key history, signing bytes, signature generation or another implementation inconsistency.

One rejected record did not establish that every record was invalid or that the whole system failed.

The review did not establish unauthorized production execution, false telemetry or deliberate misconduct.

## 6. Evidence needed for a further phase

Causal localization required authoritative signing-side bytes, key provenance or rotation records, a relevant signing implementation, or an equivalent verifiable fixture.

The public phase closed with the observation preserved and the root cause UNESTABLISHED.

A later fix or explanation would require separate evidence and a retest of the changed object.

## About this public adaptation

This public sample is a shortened, anonymized adaptation of a completed historical pilot record.

Names, product identifiers, URLs, exact dates and identifying operational details have been removed or generalized.

The findings retain the meaning and limits of the source record, but this adaptation is not its authoritative replacement.

No new system execution, reproduction or assessment was performed to prepare this PDF.

This sample illustrates selected ANDEKS methodological principles and does not constitute a new formal ANDEKS normative assessment or certification.

It does not claim use of ARE or ERA, production readiness, legal compliance or approval for deployment.

Historical findings do not establish the present condition of any system.
